Microbit motherboard wireless remote control heavy hammer car

Goals

In this lesson, we will learn to use microbit motherboard to control Magic_Car heavy hammer, which can realize forward, backward, left, right, left and right of the car, switch on-board RGB lights and headlights, and control the up and down of the steering gear of the heavy hammer car.

Programming method

(1) online programming: connect micro:bit with the computer through the USB cable, open my computer, find the MICROBIT memory disk and open it, double-clickMICROBIT.HTM, and open the browser programming page. After creating a new project, click advanced, click expand, enter the extension package address https://github.com/emakefun/pxt-magicbit.git, enter enter or search, add the Microbit extension package, and you can start programming control of the car motor.

(2) offline programming: open the offline programming software, enter the programming interface, create a new project, click advanced, click expand, enter the address of the extension packagehttps://github.com/emakefun/pxt-magicbit.git, and press enter or search, add the Microbit extension package, and then you can start programming to control the car motor.

The control principle

Microbit motherboards can communicate with each other in the form of wireless broadcast. When the program of Microbit motherboards "wireless setting" is the same digital password, Microbit motherboards can achieve simple communication through corresponding command line.

Block programming

1、 Through the previous study. Now that you know where some of the building blocks are, let's show you the new building block program for this lesson

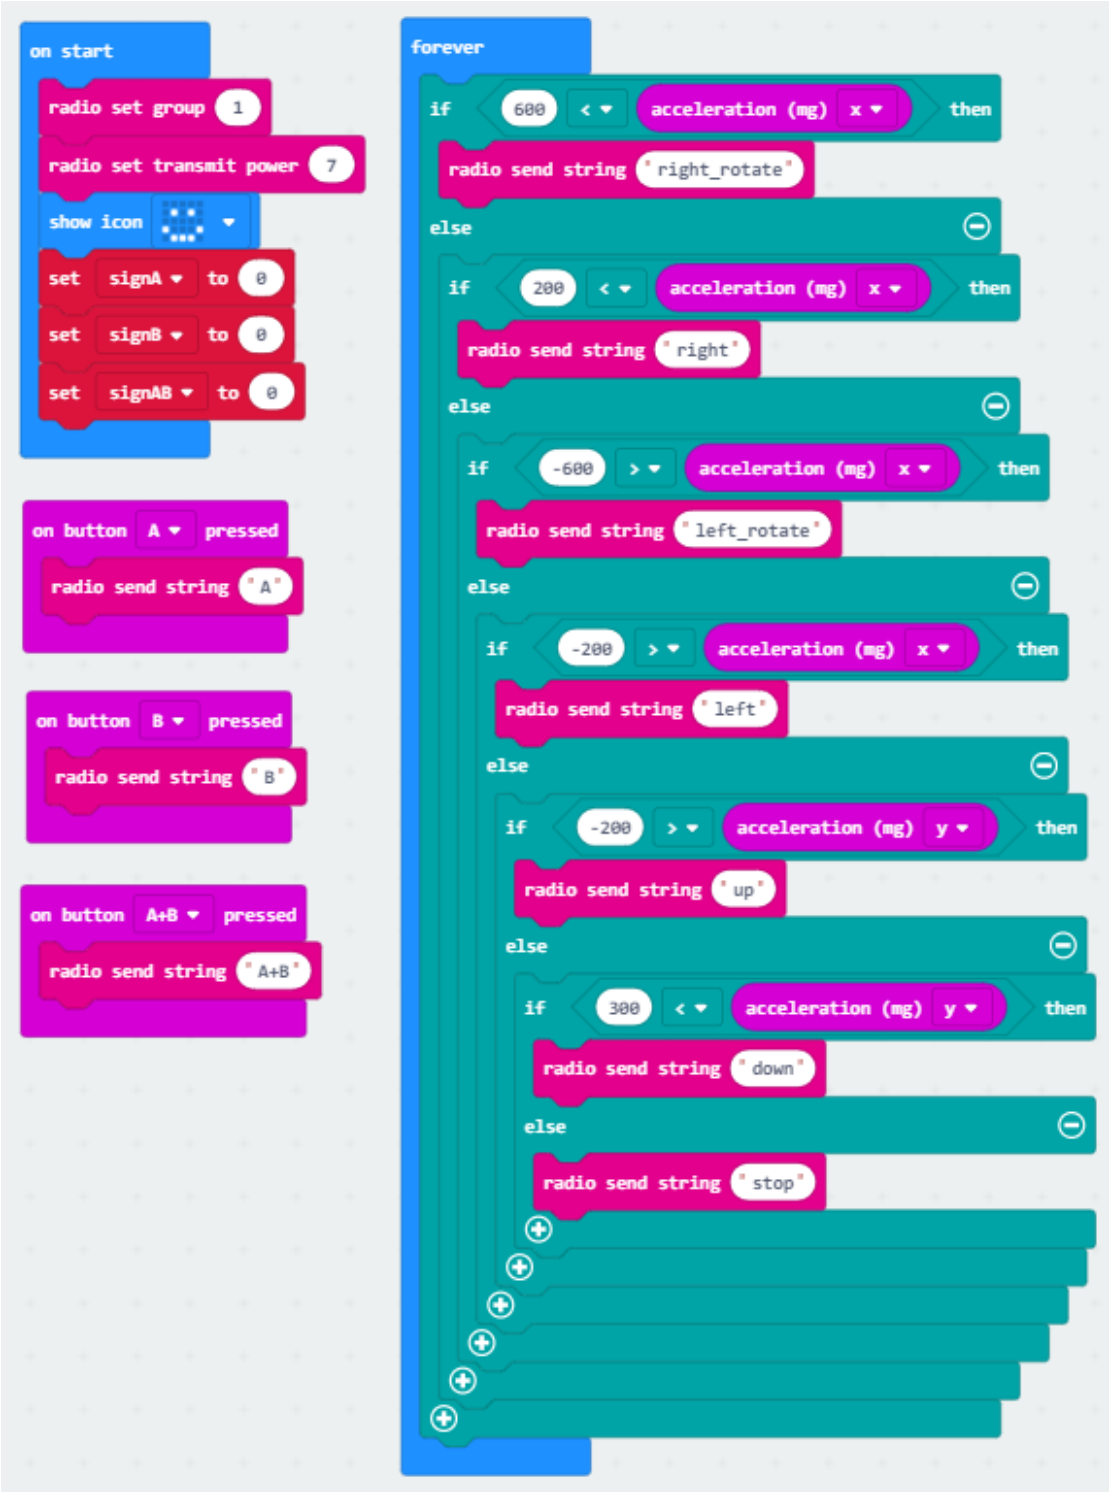
2、 Final effect of building blocks



Wiring

1. Connection of steering gear;

The car steering gear is connected to the S1 pin of the PWM steering gear of the expansion board, in which the yellow line of the steering gear is connected to the blue pin of the

expansion board, the red line of the steering gear is connected to the red pin of the control board, and the brown line of the steering gear is connected to the black GND pin of the control board.

2. Motor connection;
The motor to the left of the car is connected to the extension board M4 interface
The motor to the right of the car is connected to the expanded M1 interface
3. Connection of microbit mainboard;
The microbit motherboard of the car is the receiving motherboard, and the other motherboard is the sending motherboard, which is powered by USB cable.
4. The red wire of the headlamp is connected to the P8 red pin of the expansion board, and the other wire of the headlamp is connected to the P8 blue pin of the expansion board

The experimental results

The microbit motherboard of the Magic_Car car downloads the receiving program, and the other microbit motherboard downloads the sending program. When the program is downloaded and both microbit motherboards are powered, when the command sending motherboard tilts forward, the car advances; When the motherboard sending the command tilts back, the car will fall back; When the main board sending the command tilts to the left, the car will turn to the left, when the inclination Angle is too large, it will turn to the left in place; When the main board sending the command tilts to the right, the car will turn to the right, when the inclination Angle is too large, it will turn to the right; When the button "A" on the motherboard that sends the command is pressed, the RGB color light will be turned on or off. When the motherboard button B is pressed, the Angle of the steering gear will change up or down (the Angle of the steering gear must be adjusted according to the actual situation of assembly to achieve the best effect); When the key AB is pressed at the same time, the light will be turned off or on.
